# Miscellaneous Problems

# Dealing with missing data

We will analyse the Holzinger Swineford data included in the lavaan package.

```
library("lavaan")
summary(HolzingerSwineford1939)
```

```

```

We will fit a three-factor CFA model to the x variables in the dataset:

```
HS.model <- '
visual =~ x1 + x2 + x3
textual =~ x4 + x5 + x6
speed =~ x7 + x8 + x9
'
```

```
CD_fit <- cfa(HS.model, data = HolzingerSwineford1939, meanstructure = TRUE)
#summary(CD_fit, standardized = TRUE)
fit.inds <- c("chisq", "df", "pvalue", "cfi", "rmsea", "srmr", "aic", "bic")
fitmeasures(CD_fit, fit.inds)</pre>
```

#### Benchmark: Complete data

```
##
      chisq
                    df
                         pvalue
                                      cfi
                                                                              bic
                                              rmsea
                                                         srmr

```

Multiple imputation approach We now impute the data using package mice. We use generate five imputed datasets and use the predictive mean matching method, which is (a.f.a.i.k.) the current state of the art in missing data imputation:

```
library("mice")
m <- 5</pre>
```

```
set.seed(42)
imp_data <- mice(HSMiss, m = m, method = "pmm")</pre>

```

We see that the missing values have been imputed with different values in every dataset.

Now we use the cfa.mi() function to fit a CFA model on the imputed data:

```
library("semTools")

MI_fit <- cfa.mi(HS.model, data_list, meanstructure = TRUE)
summ_MI_fit <- summary(MI_fit)

## lavaan.mi object based on 5 imputed data sets.
## See class?lavaan.mi help page for available methods.</pre>
```

##
## Convergence information:

## The model converged on 5 imputed data sets

##

## Rubin's (1987) rules were used to pool point and SE estimates across 5 imputed data sets, and to cal We see that fitting a SEM model on imputed data is quite straightforward: we use function cfa.mi() instead

of cfa(). Using function summary(), we obtain the pooled result as a single model. The output is very similar to what were used to with a single dataset. The only difference is that with imputed data, we get t instead of z statistics for every parameter estimate:

```
summ_MI_fit
```

```
##
## Parameter Estimates:
## Warning in if (attr(x, "information") == "observed") {: the condition has length
## > 1 and only the first element will be used

                                                           0.066 5.374 0.058
```

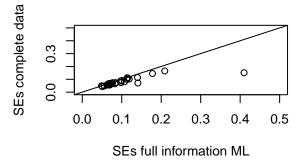

Those are a lot of numbers to compare, let's create some plots:

```
par(mfrow = c(2, 2))
plot(comp_data$LD.se, comp_data$CD.se, xlim = c(0, 0.8), ylim = c(0, 0.8),
     main = "standard errors LD vs CD",
     xlab = "SEs listwise deletion",
     ylab = "SEs complete data")
abline(0, 1)
plot(comp_data$MI.se, comp_data$CD.se, xlim = c(0, 0.5), ylim = c(0, 0.5),
     main = "standard errors MI vs CD",
     ylab = "SEs complete data",
     xlab = "SEs multiple imputation")
abline(0, 1)
plot(comp_data\$FIML.se, comp_data\$CD.se, xlim = c(0, 0.5), ylim = c(0, 0.5),
     main = "standard errors FIML vs CD",
     ylab = "SEs complete data",
     xlab = "SEs full information ML")
abline(0, 1)
```

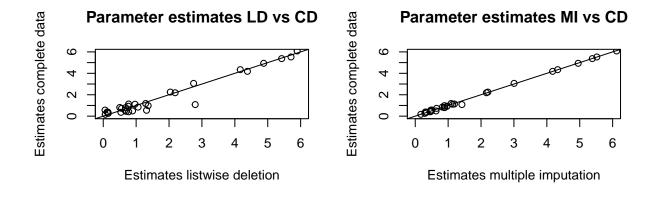

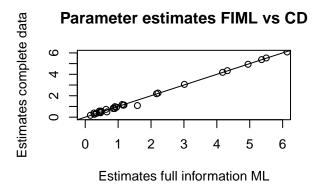

## standard errors FIML vs CD

Listwise deletion yields much larger standard errors than we would obtain if we had the complete data. The standard errors obtained with multiply imputed data are much closer to those obtained with the complete data. The MI standard errors tend to be somewhat higher, but this is what should happen, as wel did not use the full dataset with MI. The bottom-left plot indicates a similar pattern for FIML: standard errors are only somewhat larger than when analysing complete data.

```
par(mfrow = c(2, 2))
plot(comp_data$LD.est, comp_data$CD.est, xlim = c(0, 6), ylim = c(0, 6),
     main = "Parameter estimates LD vs CD",
     xlab = "Estimates listwise deletion",
     ylab = "Estimates complete data")
abline(0, 1)
plot(comp_data$MI.est, comp_data$CD.est, xlim = c(0, 6), ylim = c(0, 6),
     main = "Parameter estimates MI vs CD",
     ylab = "Estimates complete data",
     xlab = "Estimates multiple imputation")
abline(0, 1)
plot(comp_data$FIML.est, comp_data$CD.est, xlim = c(0, 6), ylim = c(0, 6),
     main = "Parameter estimates FIML vs CD",
     ylab = "Estimates complete data",
     xlab = "Estimates full information ML")
abline(0, 1)
```

The parameter estimates with listwise deletion vary much more from the parameter estimates than would have been obtained with the complete data. The parameter estimates with MI and FIML resemble those obtained with the complete data much more closer.

## Parameters relating to exogenous variables

In many SEM analyses, parameters relating to exogenous variables will often not be provided. Often, exogenous variables will be considered fixed. As a result, their (co)variances are fixed to their sample (co)variances, instead of being estimated as parameters in the model. For the model fit ( $\chi^2$  and df), this does not make a difference. But sometimes you may want to inspect the variation or associations between the exogenous variables.

```
HS_data <- HolzingerSwineford1939
HS_data$age <- with(HS_data, ageyr + agemo/12)</pre>
HS_data$sex <- HS_data$sex - 1 # to make it 0-1 coded
HS.model2 <- '
  visual = x1 + x2 + x3
 textual = \sim x4 + x5 + x6
  visual + textual ~ sex + age
HS_mod1 <- cfa(HS.model2, data = HS_data, estimator = "MLR")</pre>
summary(HS_mod1, standardized = TRUE)

```

We see that the (co)variances of the exogenous variables (sex and age) are not estimated in the model. As a results, we cannot inspect their association. To include them in the model as model parameters, we have to additionally specify fixed.x = FALSE in the call to cfa():

```
HS_mod2 <- cfa(HS.model2, data = HS_data, estimator = "MLR", fixed.x = FALSE)
